# Thousands of AI Authors

What 2,778 researchers actually think the next 20 years look like

after Grace, Stewart, Sandkühler, Thomas, Weinstein-Raun, Brauner (2024)

# One survey. One question per expert.

**2,778**

AI researchers

every NeurIPS, ICML, ICLR, JMLR, AAAI, IJCAI author from the previous year

Asked in 2023.

Same questions as 2022.

Largest expert survey of its kind. Answers sealed before GPT-4 retail launch.

The story of this paper is four moments.

Each one makes you stop.

1. A thirteen-year shift.
2. A dot plot that already aged badly.
3. A tail that will not go away.
4. What they actually fear.

# Moment 1 — The thirteen-year shift

# The question

*"When unaided machines can accomplish every task better and more cheaply than human workers."*

They call it **High-Level Machine Intelligence** (HLMI).
Call it AGI if you prefer.

Verbatim definition given to respondents, Grace et al. (2024), p. 4.

# In 2022, the aggregate answer was:

**2060**

50% probability date for HLMI

Roughly a generation away.

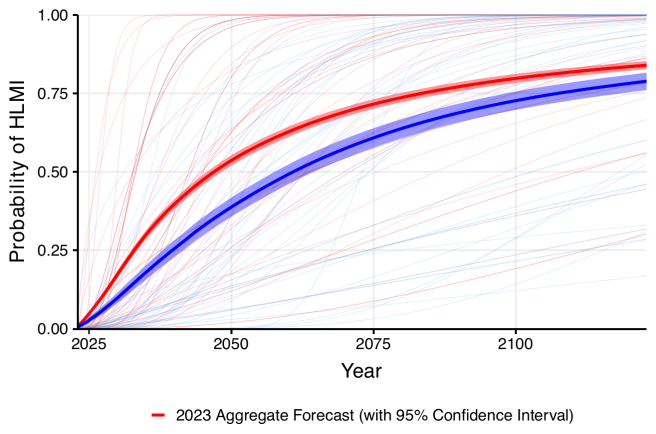
# One year later, the same experts said:

**2047**

50% probability date for HLMI

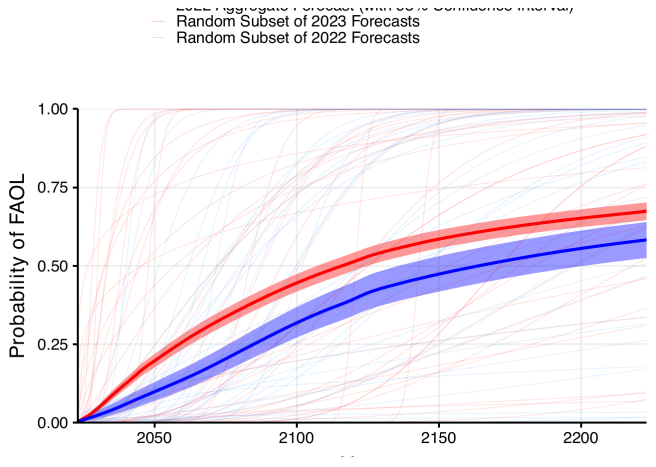
Thirteen years closer.

# The shift, as a picture



Aggregate forecast: 10%, 50%, and 90% probability dates for HLMI, 2022 vs. 2023.

# And for “all human jobs”



Full Automation of Labor (FAOL) also shifted — by 48 years.

# Read that again

The 50% date for automating
**every job on earth**
moved from 2164 to 2116.

# Moment 2 — A dot plot that already aged badly

# “HLMI” is too abstract.

So they asked about 39 specific things.

Write a *New York Times* best-seller.
Fold laundry.
Translate into a newfound language.
Do your taxes. Play Starcraft from screen video.

For each: when does 50% probability cross?

Year

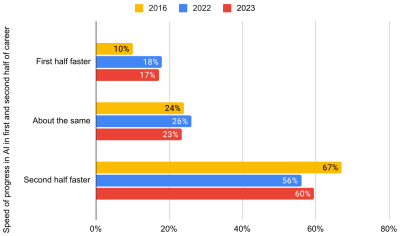
# Look at the top of that chart

- **Write a NYT best-seller.** Forecast: 2033.
- **Answer open-ended factual questions.** Forecast: 2027.
- **Write simple Python from a spec.** Forecast: 2025.

Several of these were arguably done before the ink dried.

# Pace of progress: then vs. now

of HLMI from participants answering in the fixed-year frame (54 years) was twice as far into the future as that for participants answering in the fixed-probability frame (17 years). However, it's notable that even the larger of these two is shorter than 2022's combined forecast (37 years), demonstrating a substantial shift of predictions closer to the present (Fig 18 in Appendix B).



Grace et al. (2024), Figure 4.

Respondents were asked to compare the **speed of AI progress** in the *first half* vs. *second half* of their own time working in the field.

"Career" here = years spent working in AI; median ≈ 5 years.

A clear majority say progress is **faster now** than when they started.

# The manager's question

Which of these dots
sits inside **your** core workflow?

That is the real due-diligence exercise.

# Moment 3 — A tail that will not go away

# They were also asked about outcomes.

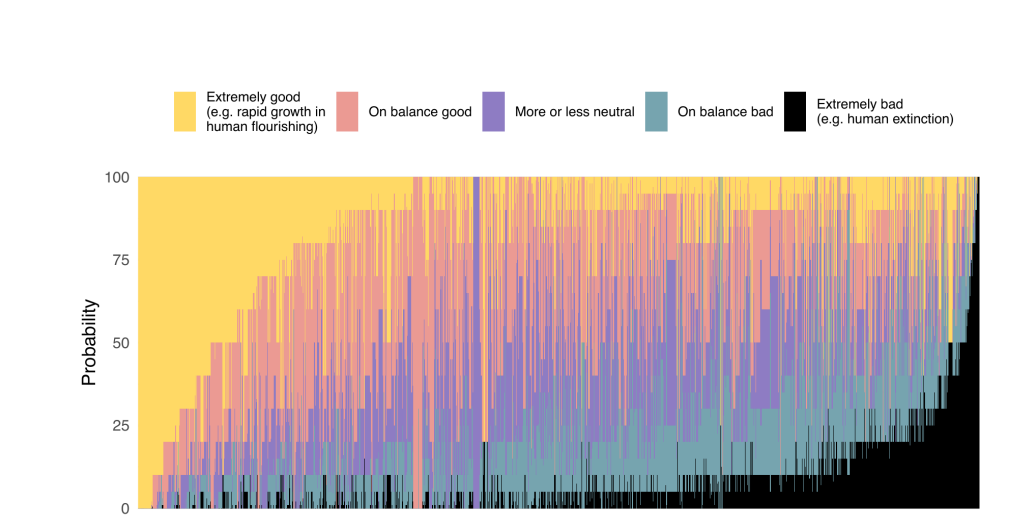
The exact question asked:

*"Assume for the purpose of this question that HLMI will at some point exist. How positive or negative do you expect the overall impact of this to be on humanity, in the long run?"*

Respondents assigned probabilities (summing to 100%) across five buckets:

extremely good · on balance good · neutral · on balance bad · extremely bad (e.g. human extinction)

Verbatim, Grace et al. (2024), footnote 5, p. 14; see also §4.2, p. 12.



Each vertical bar is one respondent, sorted by optimism.

# The number that stops a boardroom

**38%**

of surveyed AI researchers
give at least 10% probability
to outcomes *"as bad as human extinction"*.

Quoted phrase: Grace et al. (2024), abstract, p. 1 and §4.2, p. 12.

The paper's range across framings is 37.8%–51.4%.

# The extinction-tail distribution

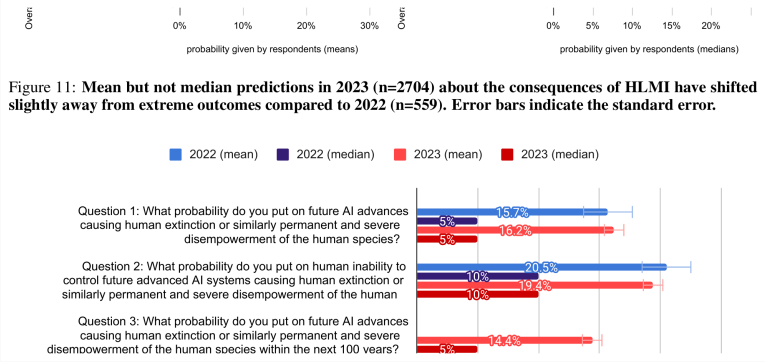


Figure 11: **Mean but not median predictions in 2023 (n=2704) about the consequences of HLMI have shifted slightly away from extreme outcomes compared to 2022 (n=559). Error bars indicate the standard error.**

Respondent-level probability assigned to extinction-grade outcomes.

# And “intelligence explosion”

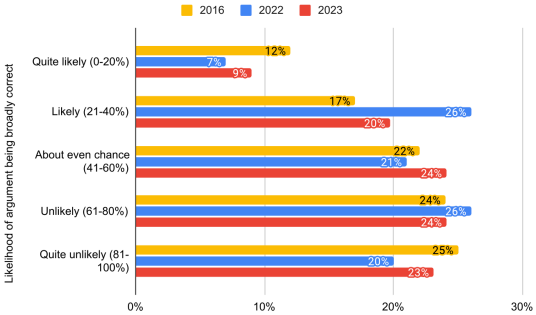

Figure 6: **Since 2016 a majority of respondents have thought that it’s either “quite likely,” “likely,” or an “about even chance” that technological progress becomes more than an order of magnitude faster within 5 years of HLMI being achieved.**

Likelihood that AI improves AI in a rapid, self-reinforcing loop.

# A calibration question (author's analogy)

"If a bridge engineer told you there's a 10% chance the bridge **collapses** — would you cross it?"

That is the shape of this tail.

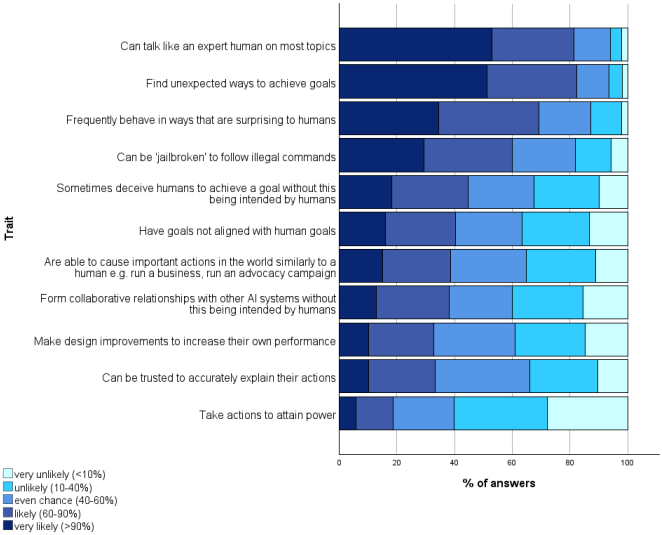
This analogy is the speaker's; it is not from Grace et al. (2024).

# Moment 4 — What they actually fear

# Not robots. Not sentience.

Two behaviours keep coming up.

**Deception.**
**Power-seeking.**



Trait
Can talk like an expert human on most topics
Find unexpected ways to achieve goals
Frequently behave in ways that are surprising to humans
Can be 'jailbroken' to follow illegal commands
Sometimes deceive humans to achieve a goal without this being intended by humans
Have goals not aligned with human goals
Are able to cause important actions in the world similarly to a human e.g. run a business, run an advocacy campaign
Form collaborative relationships with other AI systems without this being intended by humans
Make design improvements to increase their own performance
Can be trusted to accurately explain their actions
Take actions to attain power

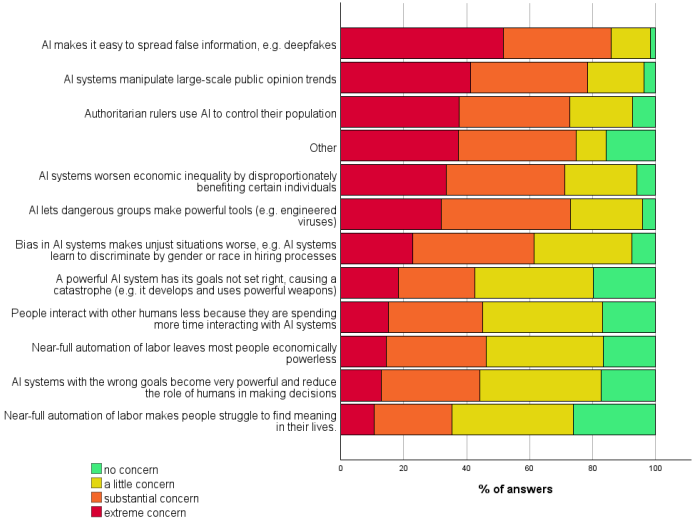
very likely (>90%)



AI makes it easy to spread false information, e.g. deepfakes
AI systems manipulate large-scale public opinion trends
Authoritarian rulers use AI to control their population
Other
AI systems worsen economic inequality by disproportionately benefiting certain individuals
AI lets dangerous groups make powerful tools (e.g. engineered viruses)
Bias in AI systems makes unjust situations worse, e.g. AI systems learn to discriminate by gender or race in hiring processes
A powerful AI system has its goals not set right, causing a catastrophe (e.g. it develops and uses powerful weapons)
People interact with other humans less because they are spending more time interacting with AI systems
Near-full automation of labor leaves most people economically powerless
AI systems with the wrong goals become very powerful and reduce the role of humans in making decisions
Near-full automation of labor makes people struggle to find meaning in their lives.

# And what they want spent on it

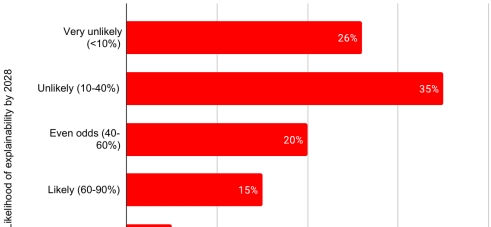
Figure 7: **Respondents' estimates of the likelihood that at least some AI systems in 2043 will have each of these traits; organized from least to most likely.**

Answers reflected substantial uncertainty and disagreement among participants. No trait attracted near-unanimity on any probability, and no more than 55% of respondents answered "very likely" or "very unlikely" about any trait. (Figure 7)

There were areas of agreement, however. For instance, a large majority of participants thought state-of-the-art AI systems in twenty years would be likely or very likely to:

1. Find unexpected ways to achieve goals (82.3% of respondents),
2. Be able to talk like a human expert on most topics (81.4% of respondents), and
3. Frequently behave in ways that are surprising to humans (69.1% of respondents)

### 3.8 Will AI in 2028 truthfully and intelligibly explain its decisions?



# So what?

# Three things to leave this room with

1. Expert timelines are **unstable**.
   Do not anchor a five-year plan on a point estimate.

2. Narrow-task forecasts **already under-shot**.
   Assume your workflow-level dot arrives early, not late.

3. The tail is **not a fringe**.
   38% of the field assigns $\geq$10% to catastrophic outcomes.

# The one number

**13**

years of expected progress
compressed into *twelve months* of calendar time.

Plan as if that could happen again.

# Thank you.

Questions.
